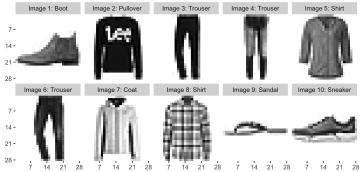
# Why Neural Networks?

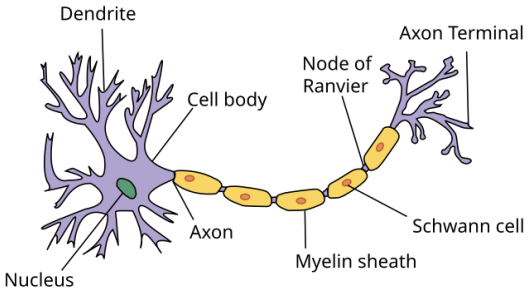
- We can find explicit formulas for some problems (no machine learning)
  - $\Delta x = \frac{1}{2} a \cdot t^2 + v_0 \cdot t$
- We can model some problems by assuming simple relationships (classical machine learning)
  - House price as a linear function of its features
  - $y = a_1 \cdot x_1 + a_2 \cdot x_2 + \ldots + a_p \cdot x_p$
- How can we classify these images?



# Why Neural Networks? Cont.

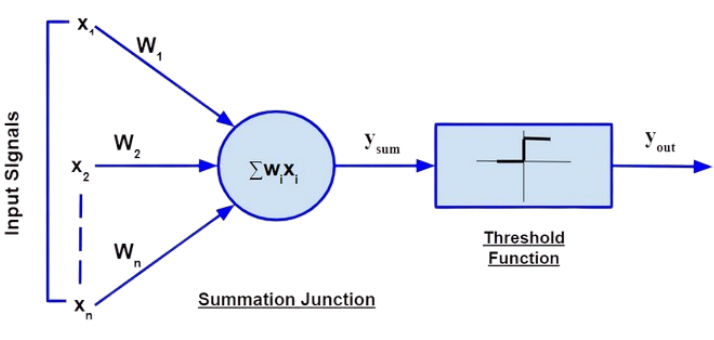
- **No explicit formula** exists to recognize a sneaker
- We intuitively recognize any sneaker
- Our brains use a **complex function** for this recognition
- **Deep neural networks** can learn this complex function

# Modelling the Brain



- Building units are neurons.
- **Dendrite:** Receives signals from other neurons.
- **Soma:** Processes the information
- **Axon:** Transmits the output of this neuron
- **Synapse:** Point of connection to other neurons

# McCulloch-Pitts Neurons

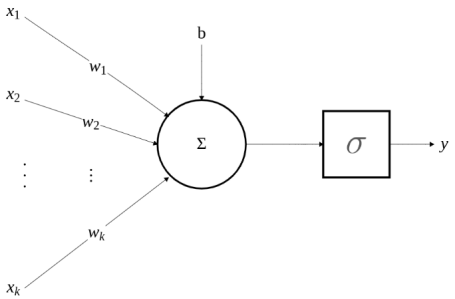


$$y = \begin{cases} 1 & \text{if } \sum_i w_i x_i - T \geq 0 \\ 0 & \text{otherwise.} \end{cases}$$

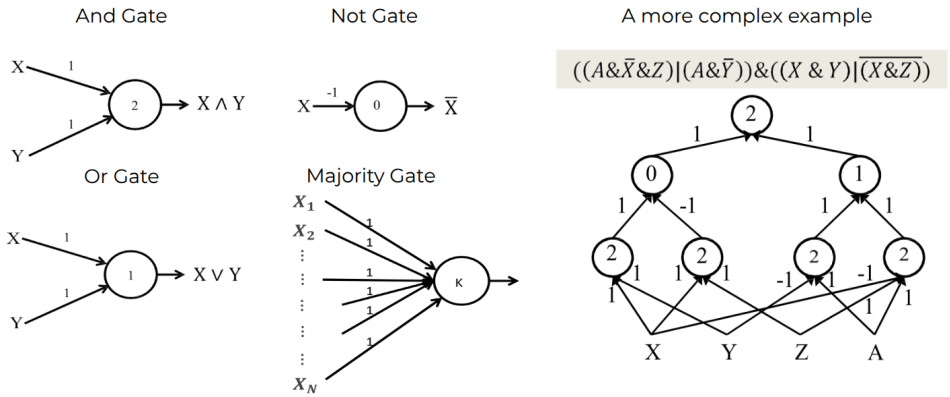
# Perceptron Reminder

The building block of each neural network is the perceptron:

- $\{x_1, x_2, \ldots, x_k\}$ : input features
- $\{w_1, w_2, \ldots, w_k\}$ : feature weights
- $b$ : bias term
- $\sigma(\cdot)$ : activation function
- $y$ : output of the neuron



# Example: Perceptron as a Boolean Gate



- A perceptron can model any simple binary Boolean gate.
- MLPs are universal Boolean functions.

# Example: MLP for Complex Patterns

- What network to learn this area?
- Example is adapted from [1].

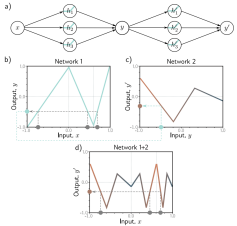
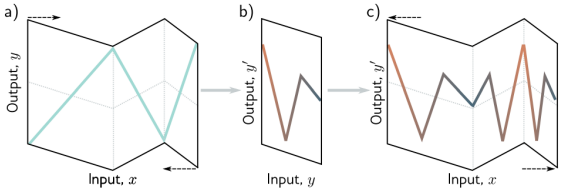
# Neural Networks for Region Classification

| Layer Type | Decision Region | Interpretation | Visualization |
|---|---|---|---|
| Single layer (perceptron) | Half-space | Linear separator defined by a hyperplane $w^\top x + b = 0$ |  |
| Two layers (1 hidden) | Closed, convex regions | Intersections of half-spaces $\Rightarrow$ convex polytopes |  |
| Three layers (2+ hidden) | Arbitrary (finite unions) | Union of polytopes; universal approximation of regions |  |

# Example: Composing Neural Networks

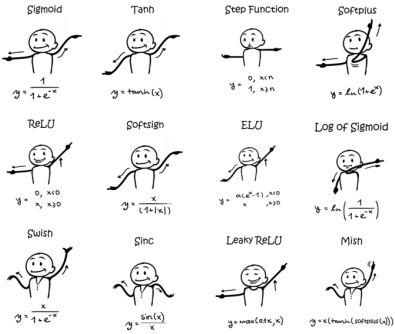
- Each layer forms a simple piecewise-linear function (ReLU units).
- Network 1 maps $x \rightarrow y$; Network 2 maps $y \rightarrow y'$.
- Composing layers increases the number of linear regions.
- The full MLP produces a more complex nonlinear function than either layer alone.





# MLP Capacity

- Increasing **width and depth** allow us to approximate **complex decision boundaries**
- An **activation function** makes a neuron's output **non-linear**, allowing the network to learn complex pattern
- It is **not limited** to Boolean or step functions
- With appropriate activation functions, neural networks can **approximate any real-valued function** (More details later)



Adapted from Sefiks

# Single Hidden Layer Neural Network

- Hidden layer pre-activation:

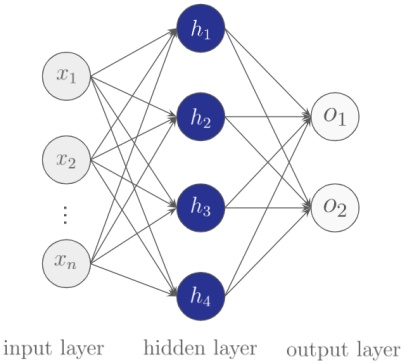
$$a_i(x) = b_i^{(1)} + \sum_j W_{ij}^{(1)} \cdot x_j$$

- Weight between neuron $i$ and $j$ in layer $\ell$: $W_{ij}^{(\ell)}$
- Activated hidden layer:

$$h^{(1)}(x) = \sigma^{(1)}(a(\mathbf{x}))$$

- Output layer:

$$o(\mathbf{x}) = \sigma^{(2)}\left(\mathbf{b}^{(2)} + \mathbf{W}^{(2)} h^{(1)}(\mathbf{x})\right)$$



# Multi-Hidden Layer Neural Network

- Let $h_i^0 = x_i$ for $i \in \{1, 2, \ldots, n\}$
- For $\ell \in \{1, \ldots, L\}$:

$$a_j^{(\ell)} = b_j^{(\ell-1)} + \sum_i W_{ij}^{(\ell-1)} \cdot h_i^{(\ell-1)}$$

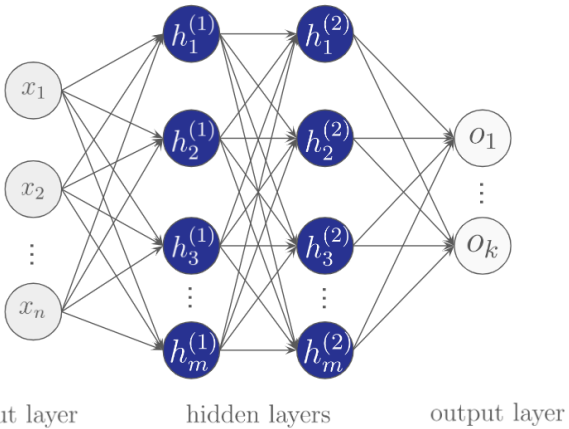
$$h_j^{(\ell)} = \sigma^{(\ell)}(a_j^{(\ell)})$$

- Learnable parameters:

$$b_j^{(\ell)}, W_{ij}^{(\ell)}$$

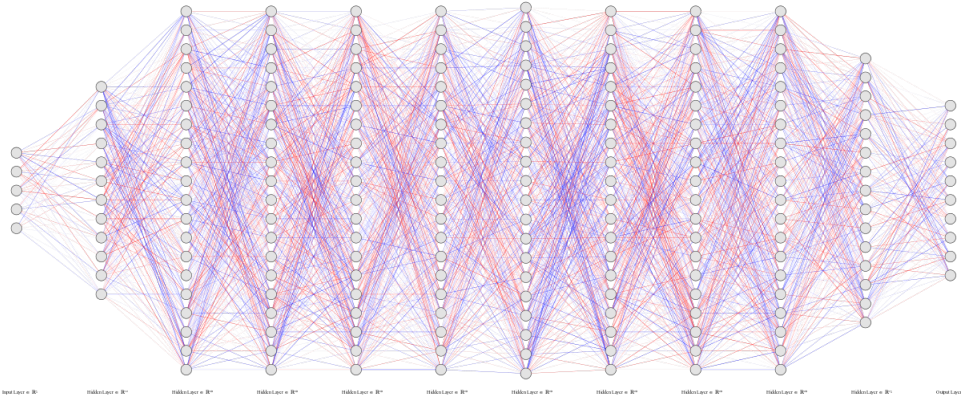
- Number of learnable parameters:

$$(n+1)m_1 + (m_1+1)m_2 + \ldots + (m_L+1)k$$



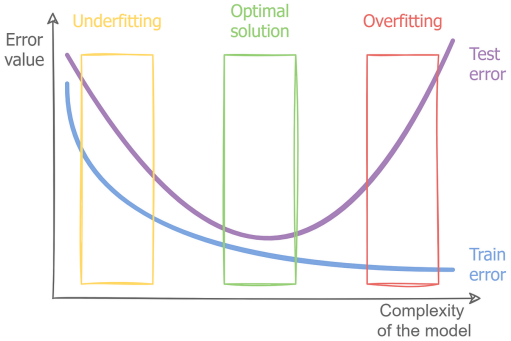
# Deep Neural Network Architecture

- More than a few hidden layers: **Deep Neural Network (DNN)**
- Designing neural network architecture is **more of an art than a science**.



# Network Width and Depth

- **Width:** More neurons, more complexity
- **Depth:** More layers, more abstraction
- **Balance:**
  - Too narrow/shallow: risk of underfitting
  - Too wide/deep: risk of overfitting



Adapted from Towards Data Science

# Universal Approximation Theorem

**Key Concept**

- The Universal Approximation Theorem states that a feedforward neural network with:
  - A single hidden layer
  - Sufficient number of hidden neurons
  - Appropriate activation functions (e.g., sigmoid)

  Can approximate any continuous function on a **compact subset** of $\mathbb{R}^n$ to any desired accuracy.

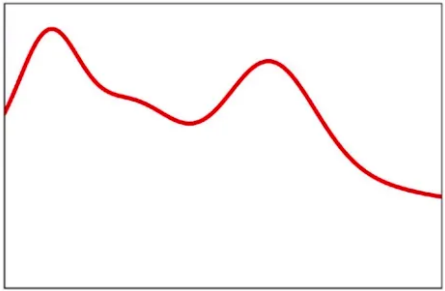
# Understanding Compact Sets

**What is a Compact Set?**

- In the context of the Universal Approximation Theorem, approximation is guaranteed on a **compact subset** of $\mathbb{R}^n$.
- A set is compact if it is both:
  - **Bounded**: Enclosed within a finite space.
  - **Closed**: Contains all its boundary points.
- Compact sets ensure certain mathematical properties that enable reliable function approximation by the MLP within that region.

# Breaking Down Complex Functions

- Idea: Complex functions can be decomposed into multiple smaller parts, each represented by a simpler function.
- By combining a series of simpler functions (like square pulses), the target function can be closely approximated.



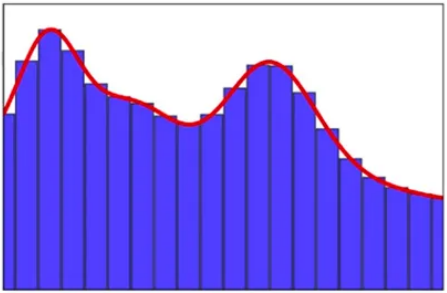


Figure adapted from Niranjan Kumar, Illustrative Proof of Universal Approximation Theorem

# MLPs as Universal Approximators

- By constructing a series of these `Square Pulse` functions, we can approximate any continuous function mapping from input to output.
- A simple 3-unit MLP with a summing output unit can generate a square pulse.
- Therefore, an MLP with enough units and the right configuration is a universal approximator!

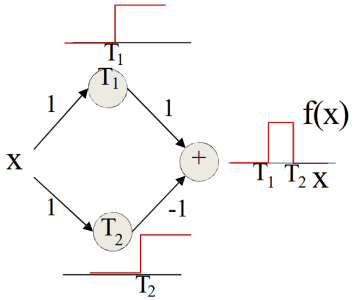

Figure adapted from Dr. Mahdieh Soleymani Baghshah, Deep Learning Course

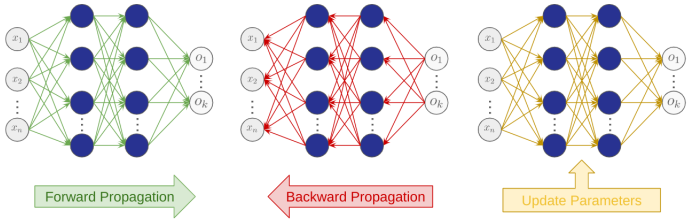
# Training Phases

- **Initialize weights and biases**: These values control how the network initially processes information (more details later)
- **Forward pass**: Pass the input through the network to get an output
- **Calculate the error**: Compare the network's output to the correct answer to measure the difference (called the 'loss' – more details later)
- **Backpropagation**: Use the loss value to adjust the weights and biases to improve the network's accuracy

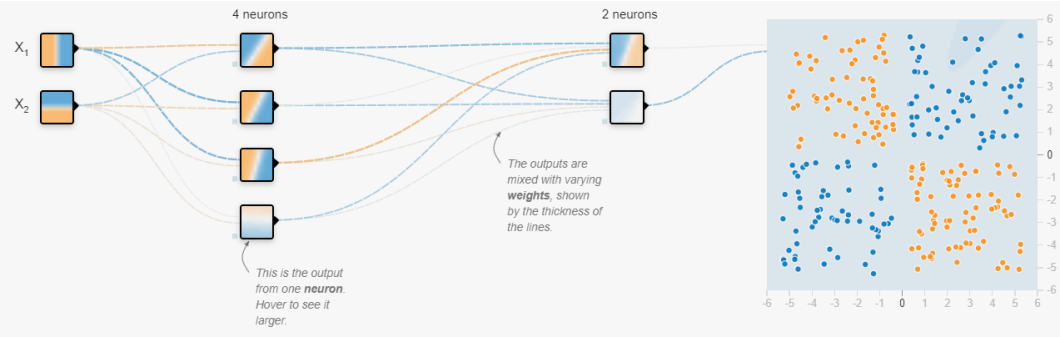


## Forward Propagation

- This is the pass where we send input data through the network to make a prediction (likely inaccurate at first).
- The prediction is made by calculating weighted sums and applying an activation function in each layer

$$o(x) = h^{(L)} = \sigma(a^L) = \sigma^{(L)}\left(b^{(L-1)} + W^{(L-1)}\sigma^{(L-1)}\left(\dots\sigma^{(1)}(b^{(1)} + W^{(1)}x)\dots\right)\right)$$

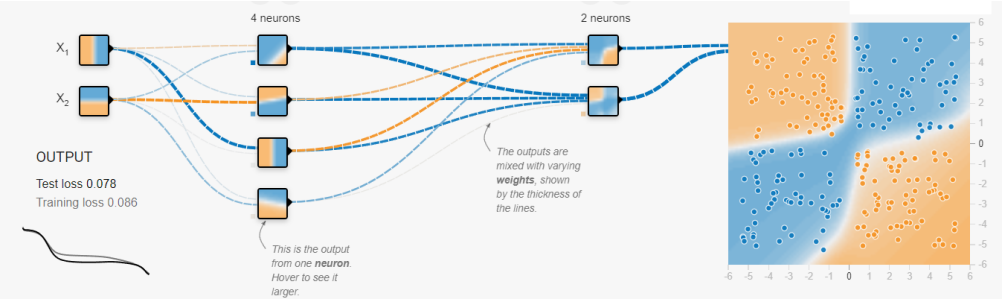
# Forward Propagation Cont.



Before making predictions. Adapted from TensorFlow playground: Daniel Smilkov and Shan Carter.

# Forward Propagation Cont.

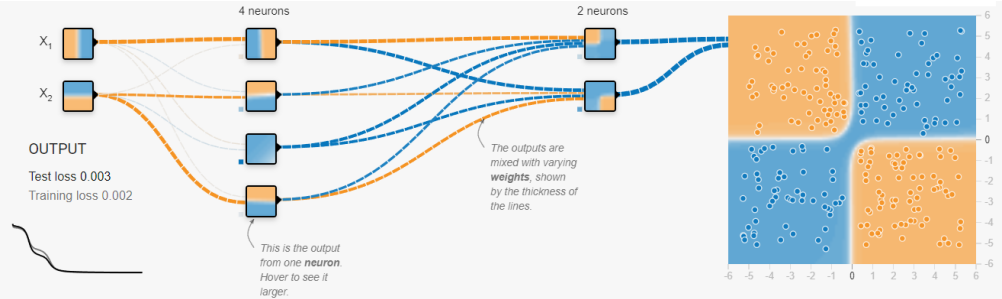
- The goal is to adjust the network's parameters to improve the predictions
- The loss is calculated after the forward pass, indicating how far off our predictions are from the true values



Loss values for predictions. Adapted from TensorFlow playground: Daniel Smilkov and Shan Carter.

# BackPropagation and Parameter Update

- The network uses the **loss** to adjust its **weights and biases** through a process known as **backpropagation**
- Backpropagation calculates how much weights should change to reduce the error
- This will be explained in more detail in the following lecture



Predictions improve as the weights get updated. Adapted from TensorFlow playground: Daniel Smilkov and Shan Carter.
